01 Executive Summary

ZEV–ZLN is a renewable-energy validation and computing ecosystem originated by ZELIONTECH LTD. ZEV is the device and platform development programme; ZLN is the token intended to support access, coordination and participation within that ecosystem. The project aims to help energy operators and service providers examine evidence about energy generation, storage, consumption and computing activity.

ZelionTech developed ZLN and one working proof of concept, ZEV Lite. The proof of concept has demonstrated energy-data capture and the recording of associated proofs on BNB Smart Chain. Development of the industrial ZEV prototype is underway. Industrial performance, certification and commercial deployment remain further milestones.

ZELIONTECH LTD and EXPOFIN S.R.L. have signed an agreement for a 50/50 joint venture. The proposed company, ZelionTech Expofin Smart Energy Ltd, remains in formation in the United Kingdom. ZelionTech leads token and software activities; EXPOFIN leads industrial device development. LOGBOT S.R.L. supports prototype and technology integration under a signed agreement. EXPOFIN Turkey is the planned production partner following prototype validation, with its final manufacturing agreement still pending.

The token allocation model totals 500 million ZLN across eight categories. The release policies distinguish tokens becoming available for approved use from actual distribution and circulating supply. Public trading has not begun. Current allocation wallets use single-signature custody and releases are managed manually. Full wallet segregation, multisig and applicable vesting or timelock mechanisms are planned. The CertiK audit has not started.

Project element	Current position
ZLN token	Deployed on BNB Smart Chain; administered by ZELIONTECH LTD
ZEV Lite	One working proof of concept; energy-data capture and proof recording demonstrated
Industrial ZEV prototype	Under development; validation and applicable certification remain ahead
Joint venture	Agreement signed; UK incorporation and final governance provisions pending
Tokenomics	Eight allocations and specified release policies agreed; several implementation parameters pending
Custody and vesting	Partial wallet segregation; single-signature custody and manual releases
Public trading	Not started; no confirmed exchange listing agreement
CertiK audit	Not started

02 Project Origin and Evolution

ZelionTech originated the ZLN token, associated software and blockchain work, and the initial ZEV proof of concept. ZEV Lite established an initial connection between captured energy data and blockchain-linked records. It provides a foundation for further development; it does not establish the performance of the industrial device.

The industrial programme combines ZelionTech's digital work with EXPOFIN's energy and device engineering activities. The parties intend to develop and commercialise the integrated project through their joint venture, with supporting technology and manufacturing relationships.

The progression is from proof of concept to industrial prototype, integration, validation, applicable certification and production. Each stage depends on the results of the preceding work and on the legal and operational arrangements needed for delivery. Detailed device design and implementation information are confidential and are outside this whitepaper's public scope.

03 The Joint Venture

The proposed joint venture is ZelionTech Expofin Smart Energy Ltd. Incorporation in the United Kingdom remains pending as of 7 September 2026. No JV registration number or incorporation date is presented. ZELIONTECH LTD is the existing UK parent company, company number 17253164; this number belongs to the parent and not to the proposed JV. The other intended shareholder is EXPOFIN S.R.L., Italy, VAT number 05419570287.

The parties have signed an agreement establishing the intended 50% ZelionTech and 50% EXPOFIN partnership. Further provisions concerning governance, IP permissions, funding, accounting and commercial operations remain to be finalised in the relevant agreements. References to the JV's future activities describe the intended operating structure while formation is pending.

The agreed planned directors are Dino Vincoletto representing EXPOFIN, and İhsan Serdar Eldek and Roula Jamil representing ZelionTech. This is a three-person board with two ZelionTech representatives and one EXPOFIN representative. Equal shareholder ownership does not mean equal numbers of board seats. These planned appointments are distinct from completed registration of directors.

Rules for resolving board disagreements remain pending. The chair, any casting vote, voting thresholds, reserved matters and shareholder exit arrangements are not represented as finalised by this whitepaper. No controlling vote or veto is inferred from either the ownership percentages or the proposed board composition.

04 Division of Responsibilities

The intended division of work assigns digital and token activities to ZelionTech and industrial device development to EXPOFIN. Integration will bring these workstreams together within the JV programme. Current token administration remains with ZELIONTECH LTD while the final JV structure is completed.

Participant	Role in the project	Position
ZELIONTECH LTD	ZLN administration, tokenomics, software and blockchain development	Current token and wallet administrator; original PoC developer
EXPOFIN S.R.L.	Energy engineering, industrial ZEV device and prototype development	Intended 50% JV shareholder and industrial development partner
Proposed JV	Integrated project delivery and planned commercial operations	In formation; detailed arrangements pending
LOGBOT S.R.L.	Prototype development and related technology integration	Technology partner under a signed agreement
EXPOFIN Turkey	Mass production and production scaling after validation	Planned role; final manufacturing agreement unsigned

These responsibilities do not themselves transfer ownership of background technology, confer patent licences or allocate tokens to partners. Ownership and usage rights are addressed separately in Section 06, and any partnership token awards are subject to Section 21.

05 Partnership Economics

The 50/50 arrangement concerns the intended shareholding and economic participation of ZelionTech and EXPOFIN in the JV. It does not divide the 500 million ZLN token allocation between the two companies. ZLN remains subject to the eight-category allocation model and the corresponding release policies.

Revenue from ZEV device sales, platform subscriptions and commercial licensing is planned to be collected by the JV. After relevant manufacturing, sales, operational, tax and other project expenditures, distributable net profit is intended to be shared 50% with ZelionTech and 50% with EXPOFIN. The final JV agreement will specify revenue collection, cost accounting and the distribution mechanism. This is a planned corporate profit-sharing arrangement; it is not a promise of fixed distributions or a right granted to ZLN holders.

ZELIONTECH LTD is the planned principal contracting and receiving entity for ZLN token sales. Funding provided to the JV from those proceeds will depend on approved budgets and documented project needs. It will not be transferred automatically or as a fixed percentage. Section 18 explains the intended use of sale proceeds.

06 Intellectual Property

ZELIONTECH LTD retains its pre-JV software, smart contracts, ZEV proof-of-concept work and associated background IP that it owns. EXPOFIN retains its own pre-JV technology and IP. Each party intends to grant the JV the usage or licensing rights needed for its operations. Granting a licence does not, by itself, transfer ownership of the licensed background IP.

The ZEV patent application must be distinguished from company-owned background IP. A patent application has been filed before TÜRKPATENT. The invention is attributed to İhsan Serdar Eldek, and İhsan Serdar Eldek and Roula Jamil are named as co-applicants. Ownership of the application currently remains with those individuals. The PCT process for seeking international protection is ongoing. No granted patent or worldwide protection is claimed. Patent grants under the PCT route remain matters for the relevant national or regional offices. [3]

No separate assignment or licensing agreement has yet been signed transferring these patent-application rights to ZELIONTECH LTD or authorising it to license the technology to the JV. Usage, licensing and authorisation arrangements for ZelionTech and the JV remain to be established through the JV and relevant IP agreements. The planned commercial licensing model therefore depends on completing the necessary rights arrangements.

New IP arising from the ZEV prototype, device technologies and developments jointly created within the JV programme will be addressed separately in accordance with the 50/50 partnership principle. The precise ownership and licensing mechanisms for that future IP remain to be defined. No exclusivity, royalty rate, perpetual licence or unrestricted sublicensing right is represented as agreed.

Device construction, engineering designs, proprietary implementation methods and detailed test information are confidential. This whitepaper describes intended capabilities, business roles and development status without publishing those materials. It does not claim that confidentiality or a patent application prevents all replication or establishes a granted exclusive right.

07 Development Status

ZEV Lite is the project's single working proof of concept. It has demonstrated energy-data capture and recording associated proofs on BNB Smart Chain. These demonstrations are limited to the proof-of-concept stage. They do not establish industrial accuracy, renewable origin, continuous operation or independent certification.

The industrial ZEV prototype is being developed. Its intended capabilities include industrial energy measurement, device authentication, detection of interference, operational continuity, lifecycle support, anomaly analysis and enterprise reporting. The implementation and effectiveness of these capabilities remain subject to development and testing.

Integration, validation, applicable product compliance and production preparation remain further milestones. Commercial device availability, production capacity and deployment dates are not committed in this edition. Specific test environments, locations and detailed proof records are not included in the public document.

08 Market Context

Growth in renewable-energy infrastructure and computing creates demand for better evidence about energy production and use. IRENA reports that global renewable power capacity increased by 692 GW in 2025. This is an installed-capacity measure, not a measure of electricity generated or of ZEV's addressable revenue. [1]

The IEA projects global data-centre electricity consumption to increase from 485 TWh in 2025 to approximately 950 TWh in 2030. That projection concerns data centres as a whole and is subject to uncertainty. It is not a forecast of demand for ZEV or returns from renewable computing. [2]

The project is intended to serve organisations that need traceable energy information for operations, customer reporting or verification processes. The size of the opportunity available to ZEV will depend on product validation, customer adoption, competitive alternatives, pricing and the reporting requirements applicable to each customer. No market-share or project-revenue forecast is presented.

09 The Verification Problem

An energy record can be useful only if the underlying measurement and its context are reliable. Errors may arise from measurement quality, incomplete records, incorrect attribution or the assumptions used to interpret the data. A record's presence on a blockchain does not resolve those issues by itself.

Blockchain-linked records can support checks on record integrity and the existence of information by the time it is recorded. They do not independently establish the truth of a physical measurement, the exact time of the physical event, the location of a device or the renewable origin of electricity. NIST describes this broader limitation as the challenge of bringing trustworthy external information into a blockchain system. [4]

ZEV's proposed value is to improve the evidence available to operators and reviewers. Measurement validation, appropriate methodologies, operational oversight and independent assessment remain important alongside the blockchain record.

10 The ZelionTech Approach

The project combines energy-data capabilities with software services and blockchain-linked evidence. The intended user experience is to examine energy information, associated verification records and reporting outputs through a coherent platform.

The development programme seeks to make records easier to attribute, inspect and use across energy and computing workflows. Its effectiveness will depend on the quality of the measurements, implementation of the supporting services and the controls applied to the overall process. The prototype must be tested against the use cases it is intended to support.

Public descriptions focus on these outcomes. Internal device architecture, construction and implementation procedures are not disclosed. The absence of those details from this paper should not be read as evidence that the intended security or performance objectives have already been achieved.

11 The ZEV Device

ZEV is being developed as a device supporting renewable-energy validation and related operational information. Intended customer-facing functions include energy measurement, evidence attribution, detection of abnormal behaviour and integration with enterprise reporting services.

The existing ZEV Lite proof of concept establishes an initial demonstrated capability. Industrial measurement performance, authentication, tamper detection and service resilience require further implementation and validation in the industrial prototype. No achieved accuracy class, product certification or production-readiness claim is made here.

The device is intended to complement the customer's operating and verification processes. It does not automatically replace legally required metering, an independent verifier or a recognised certificate. Suitability must be assessed for the particular application and jurisdiction.

12 Platform Overview

The planned ZEV platform brings together energy information, verification services, reporting and blockchain-based records. Access to the resulting services is intended for participating users, operators and authorised counterparties, subject to the eventual commercial and technical terms.

Operational information will require appropriate access, retention and availability arrangements. Those policies and the integrated platform's performance remain part of development. Blockchain records alone do not ensure that all relevant source information has been collected, retained or made available to a reviewer.

The project's security and continuity objectives apply across the integrated service. A problem in one component can affect other functions or the usefulness of the evidence. Resilience and recovery must be demonstrated through testing; they are not guaranteed by describing separate platform functions.

13 Renewable Computing

Renewable computing is a planned use of the ZEV ecosystem. The programme aims to support evidence about energy associated with computing workloads and to reward eligible network participation and actual computing activity when the relevant services become operational.

No commercial computing service, guaranteed capacity, fixed return or assured profitability is offered by this whitepaper. Economic performance will depend on factors including demand, utilisation, operating costs, energy availability and validated service performance.

The 100 million ZLN Compute Rewards and ZEV Network allocation is reserved for verified activity. Rewards are planned for monthly periods using a points-based model. Final scoring weights, the reward formula and the maximum periodic budget remain to be determined from prototype tests and economic modelling. Section 21 sets out the agreed restrictions on that reserve.

14 Carbon Data and Digital MRV

ZEV is intended to support measurement, reporting and verification workflows by providing energy information that can be examined as part of a broader evidence package. Such information may be relevant to sustainability reporting, energy attribution and assessments of emissions-related activity.

A carbon credit or environmental certificate requires the methodology, eligibility, verification and issuance process of the relevant scheme. Additionality, boundaries, emissions factors and double-counting controls are not established merely by recording energy data on a blockchain. ZEV records would be inputs to a suitable process, not automatic issuance of a credit.

ZLN is not represented as a carbon credit, a renewable-energy certificate or a quantified emissions reduction. The proposed use of ZEV information in such workflows remains subject to technical validation, appropriate methodology and acceptance by the relevant participants. No registry approval or carbon-credit issuance partnership is claimed.

15 Competitive Positioning

ZEV's intended differentiation is the combination of energy-data capture, verification records, reporting services and planned network participation within one programme. The project also combines ZelionTech's digital work with industrial development and integration partners.

These are product objectives rather than verified comparative performance results. Conventional metering, energy-management platforms, reporting services and other distributed infrastructure projects may address overlapping customer needs. Buyers will need to compare measurement quality, interoperability, total cost, service support, reliability and compliance suitability.

The whitepaper does not claim that competing approaches cannot provide trustworthy evidence, that ZEV eliminates all trust assumptions or that the device is impossible to copy. Commercial differentiation must be supported by validated product performance and customer adoption.

16 Intended Use Cases

Potential use cases include energy-asset monitoring, information about generation and consumption, operational reporting, evidence supporting sustainability workflows and attribution of energy associated with computing activity. The intended customers include energy operators, infrastructure integrators and organisations requiring reviewable energy information.

These use cases describe development and commercial directions. Their availability will depend on the industrial prototype, supporting platform, customer integration and relevant contractual or regulatory requirements. A possible use case does not establish an active deployment, signed customer order or accepted compliance outcome.

The project may also explore integration with decentralised physical infrastructure and real-world asset services. Recording information about an asset does not by itself create legal title, enforceable asset rights or an approved tokenised financial product.

17 Deployment Strategy

The intended deployment sequence begins with completion and integration of the industrial prototype, followed by validation, applicable certification work and manufacturing preparation. Production scaling through EXPOFIN Turkey is planned only after the prototypes pass the necessary testing and validation.

Commercial deployment is expected to require suitable supply, service and customer arrangements. These may include installation, maintenance, monitoring and platform support, with the actual scope set by the relevant agreements. The manufacturing agreement and detailed responsibilities for production, delivery and warranty remain to be finalised.

No named pilot site, customer location or confidential test environment is disclosed. This edition makes no commitment to a commercial installation date or deployment volume. Product and partner milestones will determine when the project is ready to offer specific services.

18 Commercial Model and Project Funding

The planned commercial model includes ZEV device sales, platform subscriptions, data-service access, lifecycle services and licensing or integration activities. Pricing, contractual terms, service levels and the contribution of each revenue stream remain subject to commercial development.

Revenue from ZEV device sales, platform subscriptions and commercial licensing is planned to be collected by the JV. Distributable net profit will be shared under the 50/50 partnership structure after the relevant costs and taxes. The final agreement will govern accounting and distributions. No revenue forecast, fixed margin or guaranteed shareholder payment is presented.

ZLN sale proceeds

Under the current plan, ZELIONTECH LTD is the principal entity intended to enter into ZLN sale agreements and receive sale proceeds. The JV's final role in token sales and receipt of proceeds remains to be determined after its legal and operational structure and the relevant regulatory assessment are completed.

Proceeds are intended primarily for token ecosystem development, technology and software development, blockchain infrastructure, security and auditing, legal and regulatory compliance, listing and liquidity preparations, marketing and general project development. These are project-financing uses. They should not be treated as recurring revenue from an operational ZEV product.

ZelionTech may provide part of the proceeds to the JV for prototype development, testing, certification, technical integration and other joint project expenses. Any such funding will follow approved JV budgets and documented project needs. No automatic transfer or fixed percentage has been agreed. The financing instrument and detailed approval arrangements remain to be specified.

Sale proceeds are separate from the unsold ZLN and the other token reserves. Spending money raised through a sale does not authorise early release, reallocation or operational use of tokens contrary to the allocation rules in Section 21. Commercial viability and development funding remain risks while the product and services are being built.

19 Ecosystem Alignment

ZLN is deployed on BNB Smart Chain, which provides the blockchain environment for the token. The use of that network does not imply endorsement, investment, a partnership or a listing commitment by Binance or any related organisation.

Potential ecosystem integrations include energy infrastructure services, reporting providers, decentralised physical infrastructure networks and applications using real-world asset information. These describe intended compatibility and business directions. They are not a list of confirmed commercial partnerships.

The project has had preliminary email correspondence concerning a potential exchange relationship, including an audit request. No formal Binance agreement, approved listing or agreed listing price exists. Exchange selection, commercial terms and admission to trading remain uncertain. No partner or exchange name in this paper should be read as guaranteeing liquidity or a future market price.

20 ZLN Utility and Network Participation

ZLN is intended to support the operation of the ZEV ecosystem through access, coordination and incentives. ZelionTech currently manages the token and associated software work. The intended utilities depend on services that remain under development or planned; deployment of the token alone does not make those services operational.

Intended function	Proposed role	Status
Energy-data services	Access to relevant platform data and reporting services	Under development
Platform and compute settlement	Participation in payments or fee settlement for eligible services	Planned; commercial and settlement parameters pending
Network participation	Eligibility and incentives for participating operators or users	Planned
Device coordination	Support for participation in the ZEV network	Planned
Governance signalling	Advisory input on future ecosystem or protocol matters	Planned
Activity rewards	Distribution against eligible, verified participation	Planned; final formula and budgets pending

The customer flow, fee denomination, any conversion process, and participation or staking requirements will depend on the final service design and published terms. No fixed stake, staking yield or reward rate is established by this whitepaper. BNB remains the network gas asset for transactions on BNB Smart Chain; any future ZLN service fees are a separate matter.

ZLN is not intended to convey equity in ZelionTech, EXPOFIN or the JV, ownership of their assets, or entitlement to corporate profits. Any future governance signalling would be advisory and would not confer corporate voting rights. The legal classification of the token nevertheless depends on the applicable law and actual arrangements, not solely on its intended utility or this description.

21 Token Distribution and Release Policies

Token model and current status

The allocation model follows ZelionTech's published tokenomics and totals 500,000,000 ZLN. The token is deployed on BNB Smart Chain and administered by ZELIONTECH LTD. The public contract reference is 0x9D9c5C7B7BfC398Ed446b7e53a8Ad8d62DCD0181. [8][11]

Parameter	Project-published specification
Network	BNB Smart Chain
Token standard	BEP-20
Maximum supply	500,000,000 ZLN
Decimals	18
Transaction tax	0%
Additional minting	Disabled
Source verification	Described by the project as an exact match on BscScan

These are the project's published specifications. They are distinct from an independent code assessment or a certification of deployed behaviour. The full allocation below matches the current project tokenomics page; the detailed release policies record the project's additional agreed terms. [11]

The CertiK audit has not started. A security assessment of the deployed contract must establish its actual supply controls, permissions, transfer behaviour and interface compatibility. This whitepaper does not represent independent verification of those code properties or a completed audit.

Current release management is administrative. Existing allocation wallets are single-signature wallets, and the authorised key holder can transfer independently. Multisig and applicable vesting or timelock controls are planned and are not currently enforcing the policies below.

Eight allocations

Allocation	Share	ZLN	Intended purpose
Compute Rewards & ZEV Network	20%	100,000,000	Verified network participation and actual computing activity
Ecosystem & Infrastructure	15%	75,000,000	Ecosystem expansion, integrations and infrastructure
Liquidity & Market Stability	15%	75,000,000	Controlled provision of exchange and market liquidity
Core Contributors (Team)	10%	50,000,000	Long-term contributor allocation
Private & Strategic Sale	10%	50,000,000	Tokens reserved for private or strategic purchasers
Public Sale	10%	50,000,000	Tokens reserved for public purchasers
Strategic Partnerships	10%	50,000,000	Awards under signed token-grant agreements
Community & Marketing	10%	50,000,000	Approved community, growth and marketing activities
Total	100%	500,000,000	Entire allocation model

Reference date and release meaning

For the schedules in this paper, launch means the first commencement of public trading in ZLN. References to TGE or launch in these policies use that event, not the earlier contract deployment or minting date. Public trading has not begun and no launch date is confirmed.

Month 1 means the first monthly anniversary after launch. Where a schedule has a six-month or twelve-month period without releases, there is no catch-up lump sum at its end. Monthly payments begin in the following month as specified below. Exact timestamps, calendar conventions and smallest-unit rounding will be documented before implementation; final rounding must not increase an allocation's total.

Availability under a release schedule does not automatically mean a transfer, a market sale or circulating supply. Unspent reserve tokens remain in their respective wallets until used for the approved purpose. Circulating supply must be assessed from actual distribution, restrictions and holdings under a stated methodology. Unrestricted tokens held by purchasers or other recipients may count as circulating without being sold on a secondary market. A reserve label alone is not sufficient evidence of exclusion. [9][10]

Summary of agreed schedules

Allocation	Available at launch	Subsequent release policy
Team	0	No release in first 12 months; 36 equal monthly instalments in months 13–48
Private and Strategic Sale	0	Purchased tokens: no release in first 6 months; 24 equal monthly instalments in months 7–30
Public Sale	100% of purchased tokens	No additional lock-up for purchased tokens
Strategic Partnerships	0	Per awarded grant: no release in first 6 months; 24 equal monthly instalments in relative months 7–30
Ecosystem and Infrastructure	7,500,000	Remaining 67,500,000 in 48 monthly instalments of 1,406,250 in months 1–48
Community and Marketing	5,000,000	Remaining 45,000,000 in 36 monthly instalments of 1,250,000 in months 1–36
Compute Rewards and ZEV Network	No automatic launch release	Monthly activity rewards once relevant services operate; maximum period budget pending
Liquidity and Market Stability	Amount not yet finalised	Initial need-based provision; unused balance retained for later CEX or DEX liquidity

For each partnership grant, its reference date is the later of first public trading and the effective date of the signed token-award agreement. Its six-month waiting period and subsequent instalments run from that reference date. Unawarded tokens do not begin vesting merely because public trading starts.

Contributor and sale allocations

The 50 million ZLN team allocation releases in 36 equal monthly instalments after the first twelve months without release, approximately 1.388889 million ZLN per month, subject to final unit rounding. The first instalment is in month 13 and the last in month 48.

Private and strategic purchasers receive their purchased amounts over 24 equal monthly instalments beginning in month 7 after launch. If the entire 50 million allocation is sold under these terms, the combined monthly amount would be approximately 2.083333 million ZLN. That example does not assume all tokens have been sold. No private-purchaser tokens become available at launch or as a catch-up payment in month 6.

The indicated private-sale price is USD 0.06 per ZLN. A public-sale range of USD 0.15–0.20 is under consideration and is not final. Relative to that prospective range, the private price would be 60–70% lower. This comparison is conditional; it is not a forecast of a listing price or a promised gain. Public-sale pricing does not determine the secondary-market price.

Public-sale purchasers are intended to have 100% of their purchased tokens available when public trading begins, with no additional lock-up. Reserving 50 million ZLN for the public sale does not establish that all of them will be sold or enter circulation at launch.

Unsold private-sale and public-sale tokens will remain in their respective dedicated reserves. They will not automatically enter circulation, move to another allocation or be used without determined sale terms. Before any future sale round, its amount, price, vesting or unlock provisions and other conditions will be set and disclosed. Later sales must specify their own timing and must not silently benefit from an elapsed earlier vesting period.

Strategic partnerships

Partnership awards will be made through signed token-award agreements. No partner has yet been promised a token allocation. A technology or manufacturing agreement alone does not establish a ZLN award. Each awarded grant follows the reference-date rule and six-month waiting period above, then releases in 24 equal monthly instalments. Tokens without an awarded grant remain reserved.

Compute rewards

The 100 million ZLN Compute Rewards and ZEV Network reserve is for gradual distribution in exchange for verified network participation and actual computing activity after the relevant services become operational. It will not be released early or used for general operational expenditure.

Participants are intended to earn points based on measurable criteria including verified compute capacity, executed computing activities, uptime, verified energy data and contribution to the network. The ZLN budget for an eligible monthly period will be allocated proportionally to participants' eligible points. No fixed ZLN amount per activity has been finalised.

The points weights, final formula and maximum monthly ZLN budget remain under development. They will take account of prototype performance, active participants, verified activity, utilisation, network scale and economic modelling. The eventual emission model must support controlled long-term use of the total 100 million reserve. No guaranteed yield, fixed emission lifetime or numerical monthly cap is presented before that work is complete.

Ecosystem and community reserves

No Ecosystem and Infrastructure tokens are planned for use or distribution before public trading. Prelaunch company development and general operating expenses will not be funded from this 75 million ZLN reserve. After launch, uses include ecosystem and infrastructure expansion, new devices and participants, technical integrations and related growth activities.

At launch, 7.5 million ZLN becomes available from this allocation. The remaining 67.5 million becomes available in 48 equal monthly instalments. Availability permits approved use; it does not require spending. Unspent amounts remain in the corresponding reserve wallet.

No Community and Marketing tokens are planned for use or distribution before public trading. Prelaunch marketing is to be conducted independently of token distribution. After launch, the allocation supports community rewards, growth programmes, campaigns and appropriate marketing under defined rules. Five million ZLN becomes available at launch, followed by 1.25 million per month for 36 months. Unspent amounts remain reserved.

Liquidity reserve

The entire 75 million ZLN liquidity allocation will not be deployed at launch. The initial amount will be based on the selected venues, required liquidity depth, initial circulating supply and market-making requirements. These inputs and the initial amount have not been finalised.

The unused balance will remain in the Liquidity and Market Stability reserve for controlled future CEX or DEX liquidity needs. No fixed linear release schedule is specified for this allocation. The name describes its purpose and does not guarantee price stability, market depth, an exchange listing or protection against losses.

Availability and circulation reporting

The fixed ecosystem and community schedules together make 12.5 million ZLN available at launch for approved reserve uses. Public-sale availability additionally depends on actual sales, and initial liquidity use remains undecided. Compute rewards and partnership distributions depend on their own activation and award conditions. These facts prevent an exact initial circulating-supply figure from being derived from the allocation percentages alone.

Elapsed month after launch	Team schedule	Ecosystem schedule	Community schedule	Combined scheduled availability
Launch	0	7,500,000	5,000,000	12,500,000
6	0	15,937,500	12,500,000	28,437,500
12	0	24,375,000	20,000,000	44,375,000
24	16,666,666.67	41,250,000	35,000,000	92,916,666.67
36	33,333,333.33	58,125,000	50,000,000	141,458,333.33
48	50,000,000	75,000,000	50,000,000	175,000,000

All values in this table are cumulative ZLN amounts under the three specified schedules, shown after the indicated month's instalment. Decimals are rounded for display. The table excludes sale tokens, partnerships, compute and liquidity, and is not a circulating-supply forecast. Actual distributions and remaining reserve balances require separate reporting and reconciliation.

22 Governance and Treasury Controls

ZELIONTECH LTD currently administers the token contract and existing allocation wallets. Some tokens have been placed in separate wallets according to purpose, but segregation into all eight final allocations is incomplete. The planned process will establish a clearly identified wallet for each allocation, reconcile existing balances and provide the addresses to the audit team.

Existing wallets are standard single-signature wallets. An authorised private-key holder can transfer independently, and manual policies do not technically prevent a transfer outside the published schedule. This creates reliance on the team's administration and key security while additional safeguards remain unimplemented.

Multisig and, where appropriate, vesting or timelock mechanisms are planned, particularly for long-term reserves. The final authorisation structure is to be documented before the audit. Signing thresholds, deployment details and the complete address mapping are not yet finalised. Separate wallet labels are not equivalent to technical locks.

The JV's rights in the ZLN economy are reserved for treatment under the relevant agreements. This does not change current operational control or create an automatic token entitlement under the 50/50 ownership principle. Corporate governance, token administration, reserve release policies and any future advisory token-holder signalling are distinct arrangements.

23 Development Roadmap

The roadmap is milestone-based. Dates are not committed where the relevant work, approvals and dependencies have not been finalised. Completion of one milestone does not guarantee completion of later stages.

Milestone	Position and dependency
ZLN token and initial PoC	Token deployed; ZEV Lite demonstrated initial energy-data capture and proof recording
JV establishment	Agreement signed; incorporation and detailed governance pending
Industrial prototype	Under development with the participating engineering and technology teams
Rights and operational agreements	Patent-use arrangements and final manufacturing terms remain to be completed
Integration and validation	Further prototype work and testing required
Token controls and audit	Wallet reconciliation and planned controls to be implemented; CertiK audit not started
Product compliance work	Applicable testing and certification to be determined and completed for intended markets
Production scaling	Planned through EXPOFIN Turkey after successful validation and agreement finalisation
Commercial deployment	Dependent on product readiness, legal arrangements and customer contracts
Compute and ecosystem services	Planned; activation and economic parameters depend on development and testing

Public trading and any exchange admission are separate conditional milestones. No confirmed trading date or venue is included in this roadmap.

24 Security and Audit Status

The CertiK audit has not started, and no CertiK audit report or finding is represented as completed. This whitepaper is project documentation and does not establish that the token or device has passed an audit, received certification or obtained regulatory approval.

A scoped smart-contract audit examines the specified code and the issues within its engagement. Accurate documentation, a defined code version and appropriate tests are relevant preparation materials. Audit findings may require remediation and follow-up review. A code audit does not by itself validate hardware performance, physical measurements, corporate agreements or the economics of the business. [5]

The industrial device is being developed with objectives for data integrity, authentication, detection of interference, operational resilience and lifecycle support. Those objectives remain subject to implementation and appropriate assessment. No completed independent hardware security assessment is claimed.

Material security considerations include key compromise, reliance on current single-signature custody, contract defects, incomplete or inaccurate source data, service interruption and the dependencies of an integrated platform. Planned controls and confidential implementation details are not substitutes for demonstrated effectiveness. Any eventual audit status must be read together with its scope, date, findings and the version assessed.

25 Leadership

The following leadership roles support the project across ZelionTech and EXPOFIN workstreams. They are distinct from the planned three-person JV board described in Section 03. An executive title does not by itself establish a registered directorship or a particular voting power.

Name	Published role
Ihsan Serdar Eldek	Co-Founder and Chief Executive Officer
Allam Jamil	Deputy Chief Executive Officer and Chief Financial, Investment and Data Officer
Roula Jamil	Co-Founder and President
Francesco Di Bernardo	Director of Legal Affairs and Corporate Governance
Dino Vincoletto	Chief Renewable Technology and Energy Validation Officer
Alessio Munerato	Chief Infrastructure and Cybersecurity Officer
Luigi Benacchio	Chief Information Officer
Antonio Guadagnino	Director of Compliance and Regulatory Affairs

Ihsan Serdar Eldek leads corporate strategy and executive direction. Allam Jamil supports executive delivery, financial and investment planning, data-informed performance management and tokenomics strategy. Roula Jamil leads international operations, organisational development and commercial growth activities. Legal, engineering, infrastructure and compliance workstreams support the broader development programme through the respective leadership roles.

Public contact for Allam Jamil: a.jamil@zeliontech.com. General project information: www.zeliontech.com.

26 Project Partners

EXPOFIN S.R.L. is the intended 50% JV shareholder and industrial engineering partner. Its role centres on the ZEV device and prototype development within the integrated programme. The existing company is distinct from the proposed JV and from EXPOFIN Turkey's planned manufacturing role.

EXPOFIN Turkey is expected to carry out mass production and production scaling after the ZEV prototypes are completed and validated. Capacity, standards, costing, delivery, warranty and related responsibilities will be specified separately. The final mass-production agreement has not been signed. There are no plans to grant it independent IP ownership over ZEV or ZLN; any operational usage rights will be defined by the relevant agreements.

LOGBOT S.R.L. is a technology partner under a signed agreement for the ZEV project. It supports hardware and IoT-related prototype work, connectivity, data collection and technical integration within the agreed scope. This high-level role does not imply that a production system is already deployed or that LOGBOT has received any token allocation or independent patent rights.

27 Legal and Risk Disclosures

This whitepaper describes the project's current position, intended uses and planned economic arrangements as of 7 September 2026. Planned features, commercial services, financing arrangements and release mechanisms remain subject to their stated dependencies. It is not a guarantee of delivery, admission to trading, regulatory permission, profitability or token value.

Participation and applicable requirements

ZLN sales are planned only in eligible countries where the necessary legal and regulatory requirements are satisfied. The intention includes individual and retail participants, subject to local legislation, applicable KYC and AML requirements and investor eligibility rules. Restricted jurisdictions and jurisdictions where requirements are not satisfied will not be accepted. The final eligible and restricted country list remains subject to legal and regulatory review.

UK activities must be assessed under the relevant UK requirements, including applicable financial-promotion rules. EU activities require separate consideration of MiCA and other applicable law. The applicability of a regime depends on the token's characteristics and the activities and markets involved. UK incorporation, a utility description or an eventual security audit does not establish that a sale or promotion is legally permitted. [6][7]

The final offering structure, participation terms and jurisdiction-specific requirements are not represented as approved or complete. This document does not assert that a KYC process alone meets all offer, marketing or trading requirements. Legal classification and any required disclosures or regulatory steps must be resolved for the intended activities.

Principal risks

Development and delivery risk: The industrial prototype and supporting services may take longer, cost more or perform differently than intended. Testing, certification, integrations, agreements or customer adoption may prevent a planned service from launching.

Corporate and IP risk: JV incorporation and final governance provisions are pending. The ZEV patent application is individually owned, and relevant company/JV rights have not yet been granted through the intended agreements. Commercial use and licensing plans depend on completing appropriate permissions and contractual arrangements.

Custody and contract risk: Current wallets use single-signature custody and administrative release controls. Key compromise, errors or transfers outside policy may cause losses. The deployed contract has not undergone the planned CertiK audit, and future controls may introduce further dependencies requiring assessment.

Data and service risk: A blockchain record may preserve inaccurate or incomplete information. Device performance, data availability, integration, external services and operating processes can affect the evidence and services provided.

Token and market risk: No exchange listing, market depth, price or continuous ability to sell is guaranteed. Token value can be volatile and purchasers may lose all amounts paid. Release availability, actual distribution and circulating supply are different measures. Future distributions can affect market conditions even when they follow the agreed schedules.

Economic and regulatory risk: The project relies on development funding and uncertain future adoption. Reward formulas and several budgets are unfinished. Changes in applicable rules, classification or market access may constrain sales, services or the usefulness of the token.

The intended utility of ZLN does not establish an investment return, corporate profit entitlement, carbon-credit value or a right to underlying energy assets. Participation decisions require assessment of the final applicable terms and the participant's circumstances. No disclaimer in this document removes obligations or rights that apply under law.

28 Project Outlook

ZEV–ZLN has an initial token and proof-of-concept foundation and an industrial prototype under development. The next work is to complete the device and platform programme, establish the necessary corporate and IP arrangements, implement the planned token controls and undertake the relevant testing and independent reviews.

The project will need to demonstrate that its proposed energy evidence, services and participation model are useful and economically sustainable. The agreed token allocation and release framework provides a documented basis for that work, while its unimplemented elements and remaining uncertainties are disclosed throughout this edition.
